International GEMS Workshop, 15 October 2013

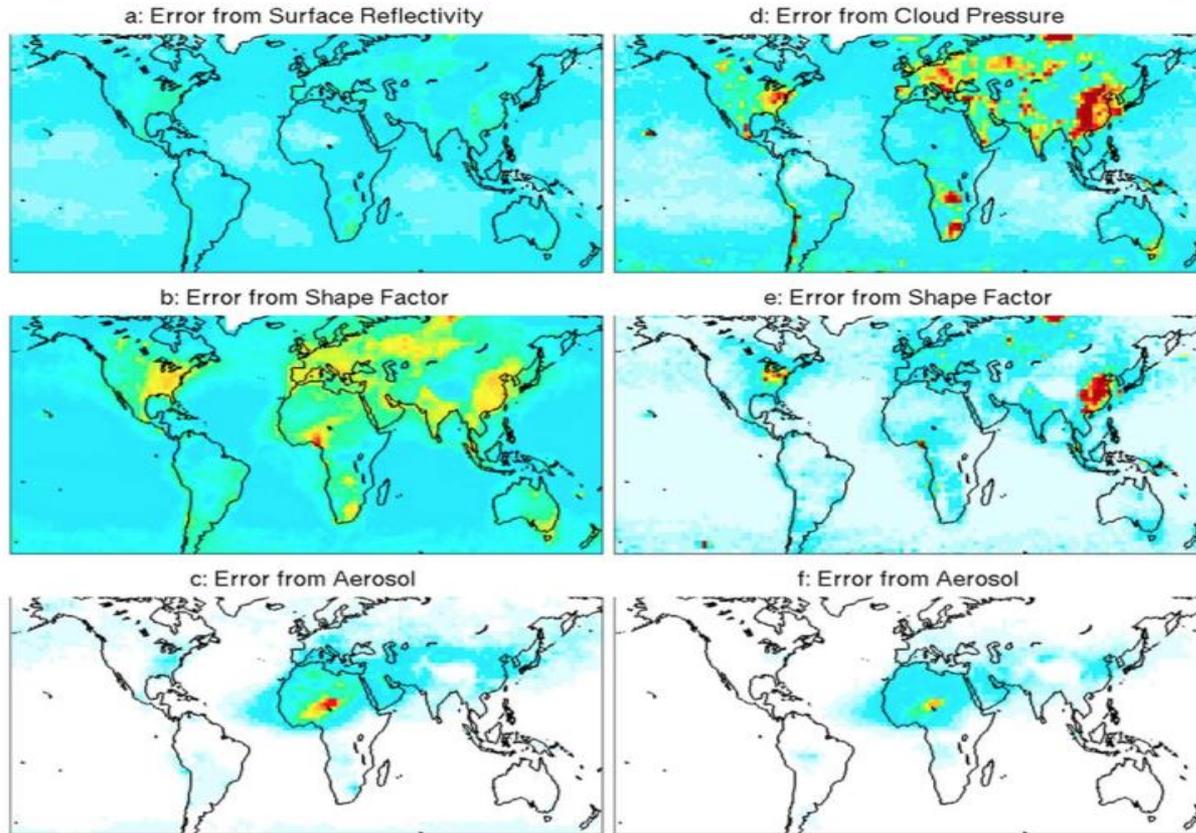

SO₂ retrieval error from SCIAMACHY and OMI

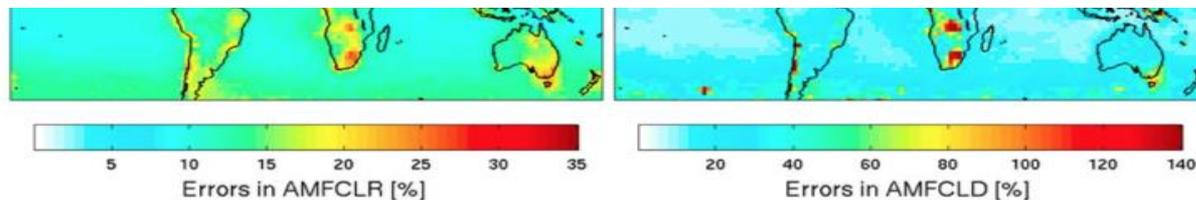

The retrieval error is dominated by the spectral fitting precision over remote regions.

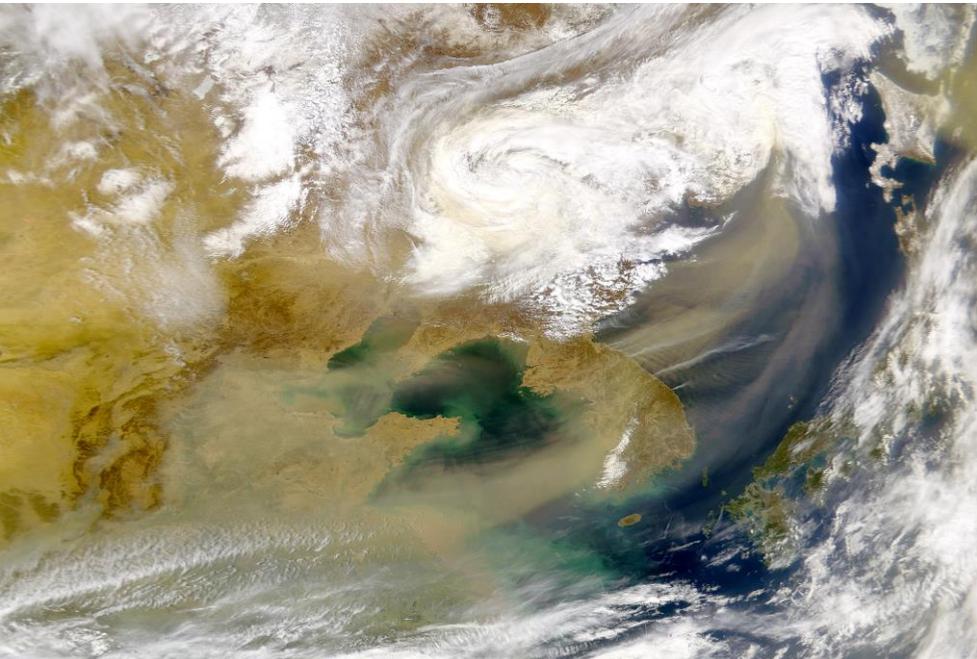

The AMF calculation becomes a more important contributor to the total error, especially in East Asia where large SO₂ emissions occur.

AMF errors are due to uncertainty in clouds, SO₂ vertical profiles, surface albedo, and aerosols.

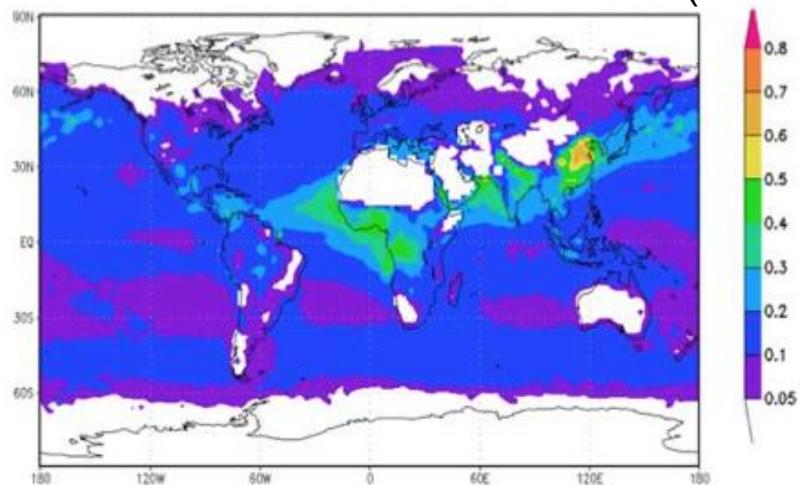

The largest contributor to the annual mean AMF error is the SO₂ shape factor (Lee et al., 2009).

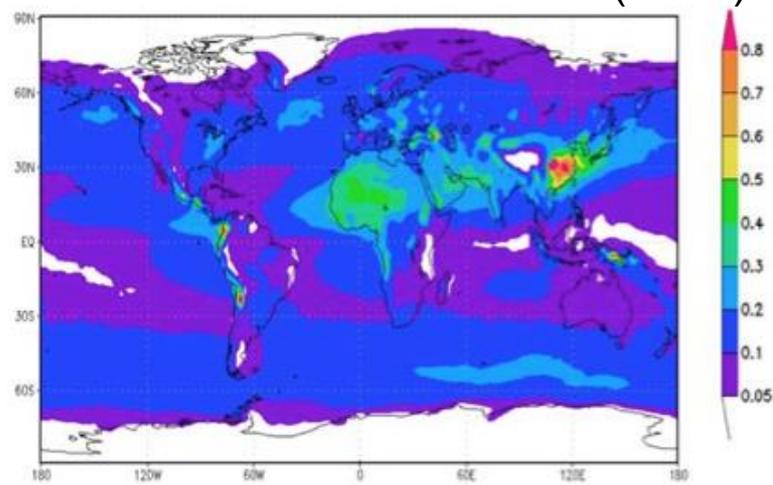

Annual AOD from MODIS/Terra (2001)

(a)

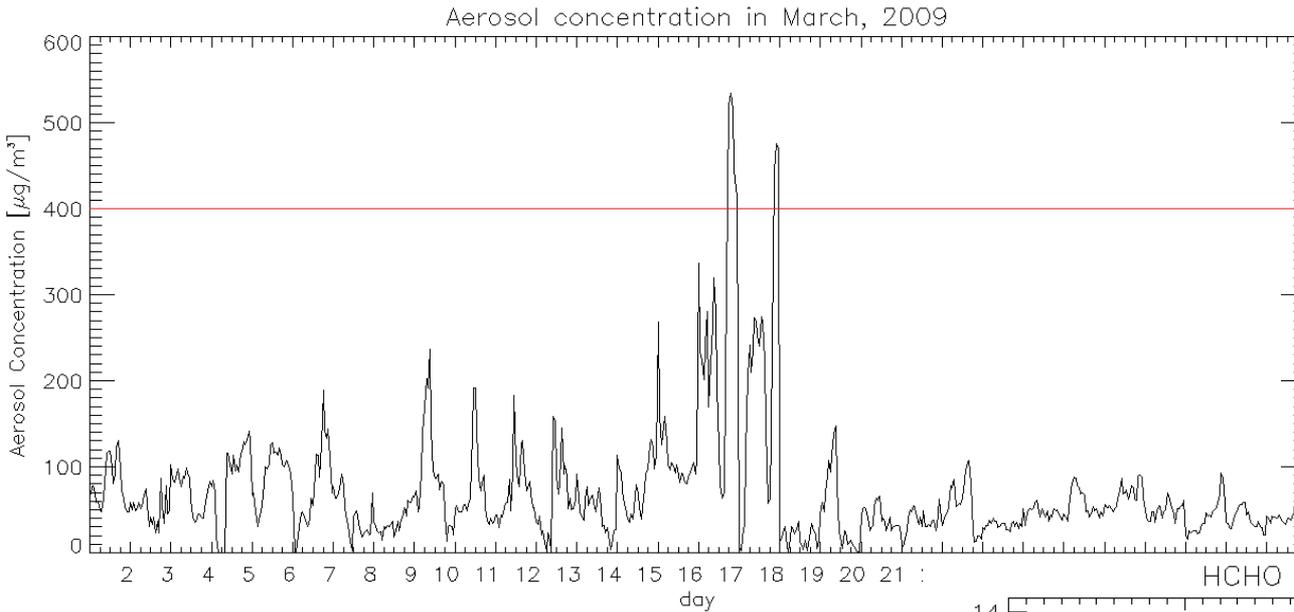

AOD from IMPACT model (2001)

(b)

Feng et al. (ACPD, 2013)

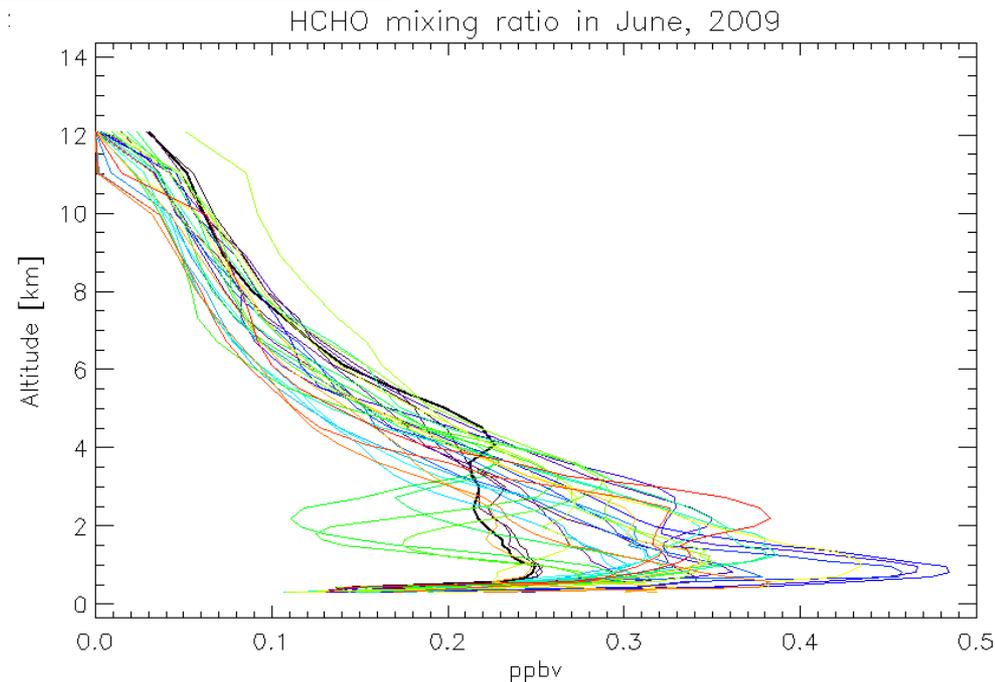

Variation of Aerosol and HCHO vertical profile

✓ Dust storm often occurs over East Asia in Spring

✓ HCHO vertical profiles can vary over time

Aerosols and vertical profiles of HCHO vary hourly.

Objectives

- Examine the sensitivity of GEMS HCHO measurements in East Asia with respect to local AMF calculations focusing on temporal variability.
- Examine the factors (shape vs. aerosol) affecting AMF calculations in East Asia.

Synthetic simulation of HCHO retrieval

Chemical transport model

Absorption cross section

Model descriptions and retrieval options

Chemical transport Model

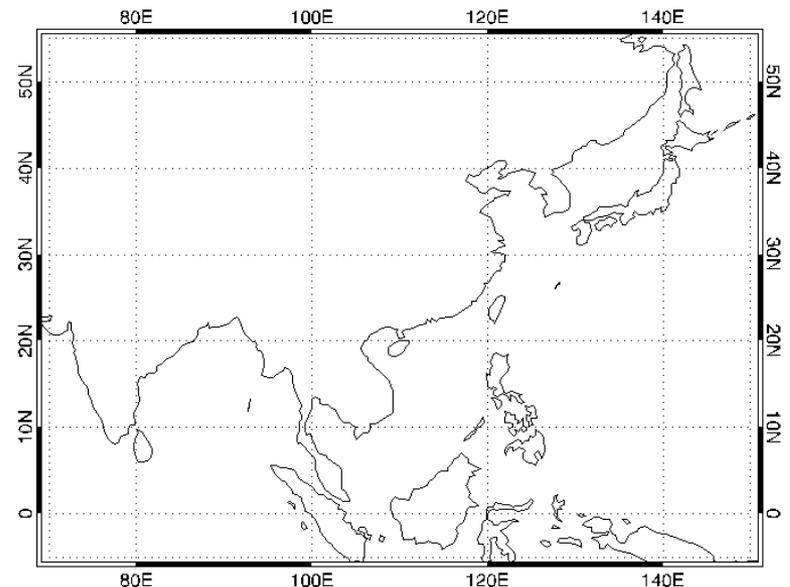

- GEOS-Chem version 9.1.2
- Meteorological field : GEOS5, MERRA
- Simulation period : June (2006, 2009)
- Resolution : 2x2.5
- Anthropogenic emissions from Streets et al. (2006)
- Biogenic emissions from MEGAN
- Biomass burning emissions from GFED3

Retrieval options

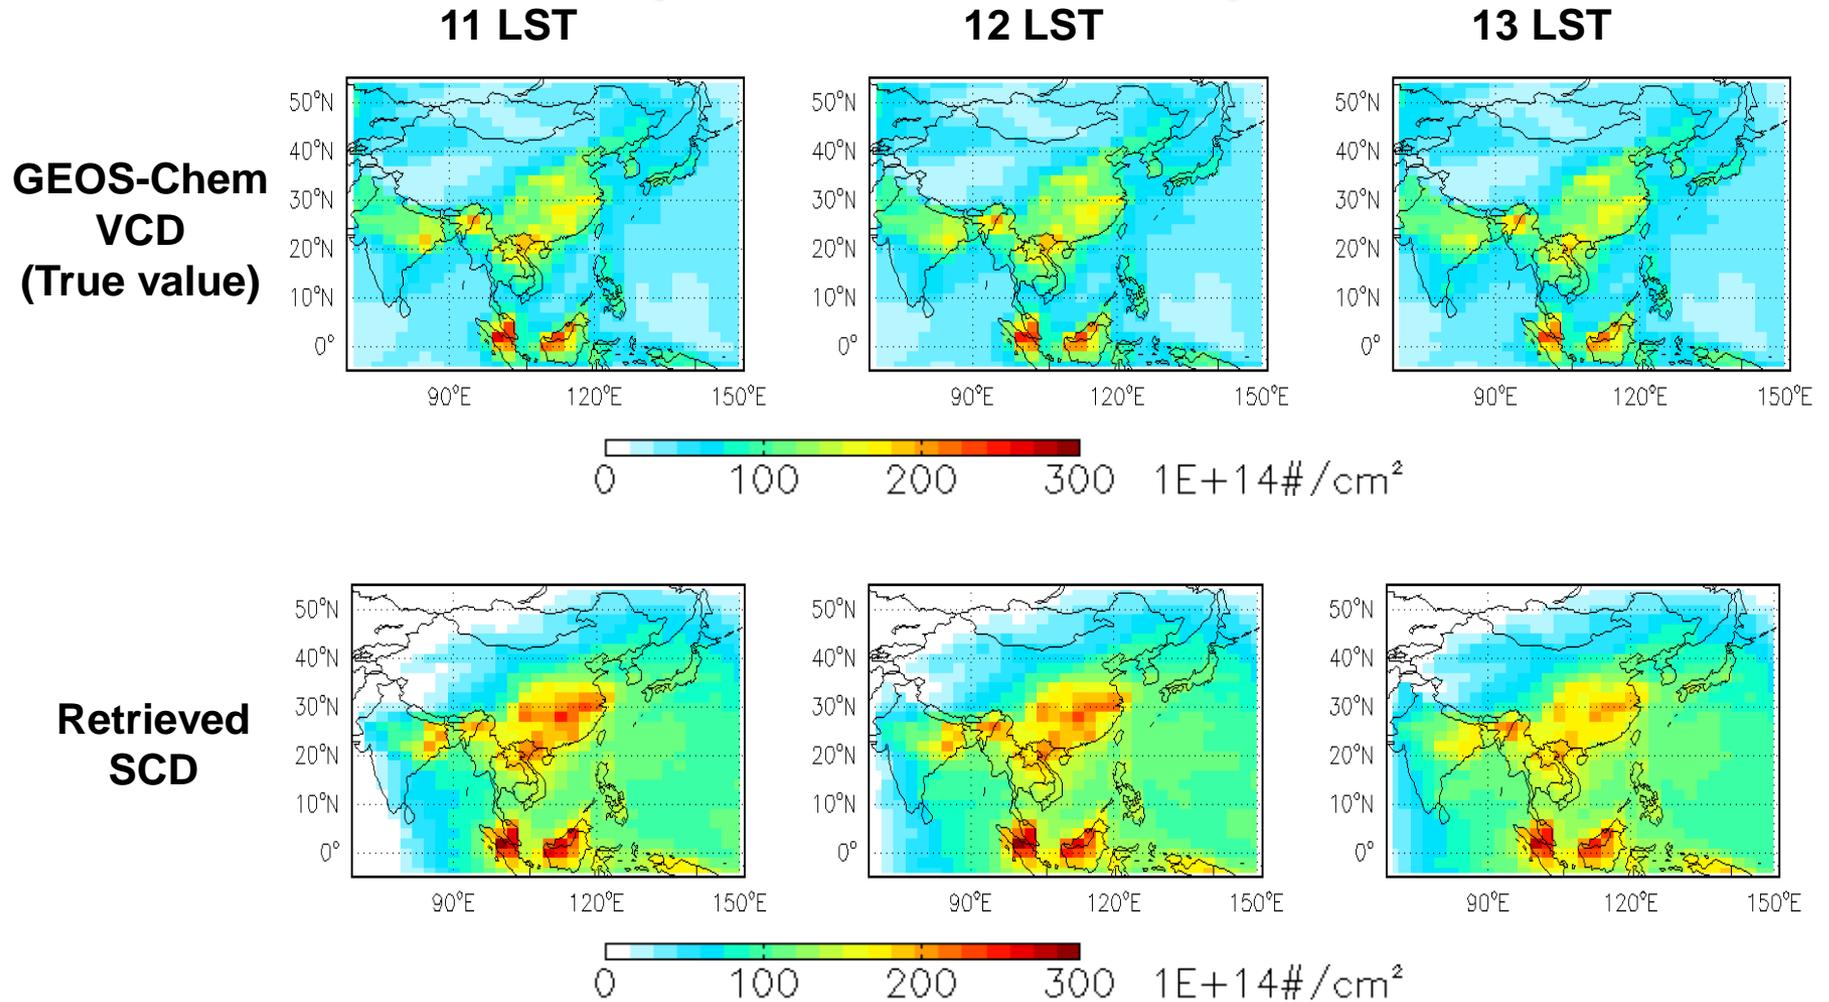

- ◆ Fitting window : 327.5-358.0 nm
- ◆ Reference spectra
Computed ring spectrum
O₃ at 228, 273 K (Brion)
NO₂ at 220 K
HCHO at 300 K

Radiative transfer Model

- VLIDORT v2.4rt (R.J. Spurr, 2006)
- 300-500 nm with 0.2 resolution
(No convolution and no any errors)
- surface albedo : 0.05
- O₃, NO₂, HCHO, SO₂ (Use O₃ of SCIATRAN data in the stratosphere)
- AOD, SSA, ASYM at 300, 400, 600, 999 nm

Simulated HCHO VCD and retrieved SCD (June 21, 2009)

We apply monthly mean AMF and hourly mean AMF to the SCD.

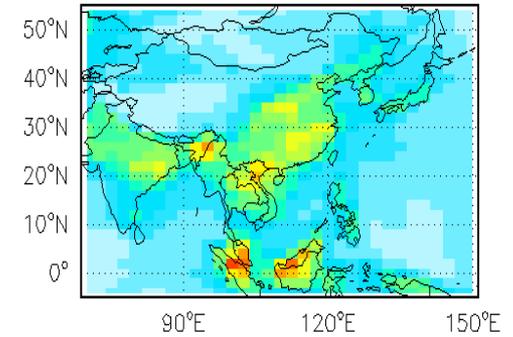

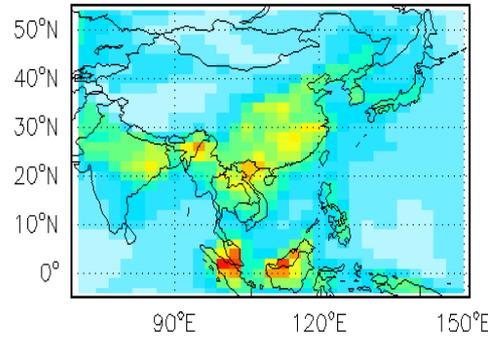

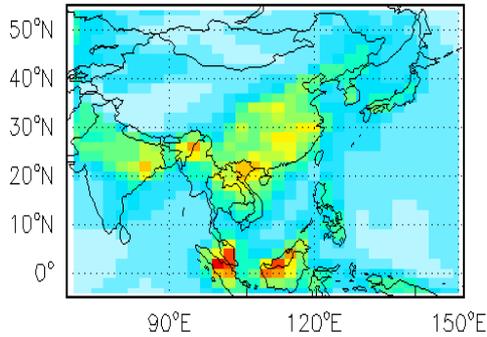

Hourly mean HCHO vertical abundance (June 21, 2009)

Using
monthly
AMF

Using
hourly
AMF

Retrieval with hourly AMF reproduces the spatial variability of HCHO VCD better than that with monthly AMF.

Monthly AMF

R=0.84

Slope=0.99

Hourly AMF

R=0.91

Slope=0.97

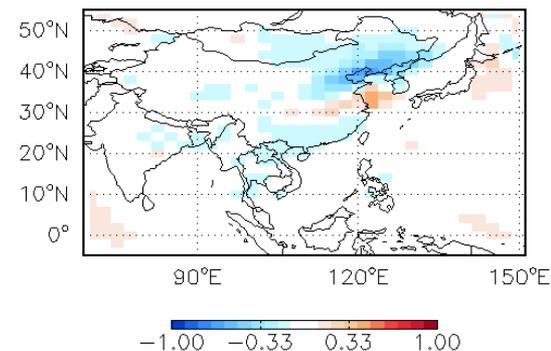

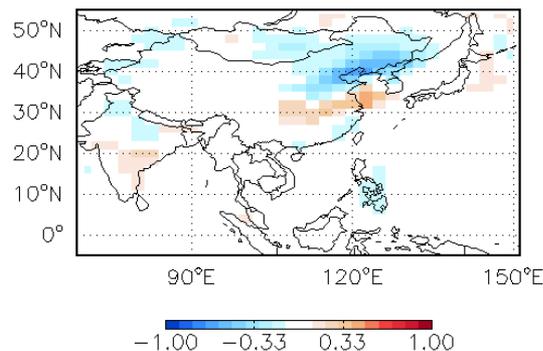

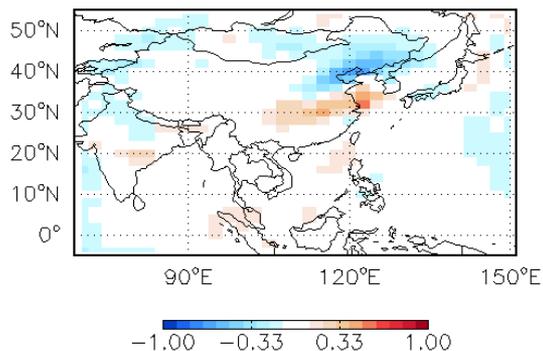

Differences (Hourly-Monthly) between monthly and hourly AMF values are mainly due to the presence of aerosols

Min. relative error	-71 %	-71 %

Monthly mean OMI HCHO VCD: composite on 1°x1° for June, 2006

HCHO VCD with hourly AMF

OMI HCHO VCD

- The figures shows the composite of OMI HCHO VCD for a month (June,2006)
- We calculated local hourly AMF at 14 LCT and applied it to OMI SCD to obtain OMI VCD.
- **Difference between our calculation and the OMI standard product is 19 % for the domain average.**

Summary

- Presence of aerosols may have a significant effect on AMF calculation for the HCHO observations by GEMS in East Asia.
- Not only the total aerosol loading (AOD) changes but also chemical composition (SSA) changes could be an important factor to AMF estimation; Better to account for high temporal variability.
- When we apply hourly AMF to OMI results for a month (June, 2006), our estimation decreases by 19% relative to the OMI standard products in East Asia (need to be further validated by comparing with other independent observations)

Future work

- Validate by comparing our calculation with other independent ground or aircraft observations in the GEMS domain.
- Hourly variation of aerosol optical properties needs to be accounted for in AMF calculation for GEMS.
- How do we accomplish this? Using satellite retrieved optical properties of aerosols can be an option.
- How can we deal with uncertainties of satellite measured aerosol optical properties (e.g. SSA)?
